I. Population Initialization

Generation of a population (set) of solutions with two possible options:

- **Random generation**, where **Size** represents the population size (number of solutions to generate).
- **Loading** a **population** of solutions from a **CSV file**.

Example of a CSV file containing a population of solutions generated within the search space of the F1-UM function.

	A	B	C	D	E	F	G	H	I	J	K	L
1	-52.900000	91.450000	-68.310000	63.980000	-73.780000	-9.510000	-59.240000	-67.310000	54.150000	21.350000	46.940000	-43.320

II. Population Evaluation

The "Evaluate Population" button displays:

- The best fitness value in the population (the solution that minimizes the objective function).
- The worst fitness value in the population.
- The population solutions and the best solution found so far (**search history**) in two dimensions using a **scatter plot**.

The scatter plot also displays contour lines. The contours are used to:

- **Visualize the structure of the problem:**
  - Where is the minimum located?
  - Is the function convex?
  - Are there multiple local minima?
- **Understand the difficulty of the optimization problem.**
  - For example:
    - Regular circular contours (as in F1) indicate a simple problem.
    - Numerous oscillations (as in F9) indicate a multimodal problem.
    - A narrow valley (as in F5) indicates a problem that is difficult to converge.
- **Observe the behavior of the population:**
  - By adding the population solutions to the scatter plot, we can verify:
    - Whether the solutions are moving toward the global minimum,
    - Whether they are trapped in a local minimum,
    - Their exploration versus exploitation capability.

To display a given solution $x = (x_1,\ x_2, \dots,\ x_D)$ in a scatter plot, we consider only the first two decision variables $x_1$and x_2.

III. Running Multiple Populations

The "Evaluate" button generates randomly multiple populations and returns the results of all the generated populations

The results are calculated as follows :

Metric	Formula	Description	Measure	Goal
Best	$\text{Best} = \min_{1 \le i \le R} B_i$	$\boldsymbol{B_i}$: best fitness value in the population during run i. $\boldsymbol{R}$: number of runs.	Quality solutions	**Smaller Best:** Algorithm can reach high-quality solutions.
Worst	$\text{Worst} = \max_{1 \le i \le R} W_i$	$\boldsymbol{W_i}$: worst fitness value in the population during run i.	Quality solutions	
Mean (average error)	$\text{AVG} = \frac{1}{R}\sum_{i=1}^{R} B_i$		Quality solutions	**Smaller AVG:** Better overall performance.
Standard Deviation	$\text{STD} = \frac{1}{R-1}\sum_{i=1}^{R}(B_i - \text{AVG})^2$		Algorithm stability	**Smaller STD:** Algorithm behaves in a stable manner. **Smaller STD + Larger AVG:** The algorithm is: . Converging too quickly. . Losing diversity (poor exploration). . Getting trapped in a local optimum. **Smaller STD + Smaller AVG:** Ideal balance.

Pseudo-code to Compute Performance Metrics over Multiple Runs

$\boldsymbol{AVG} \leftarrow \mathbf{0}$
For $\boldsymbol{i} \leftarrow \mathbf{1}$ **to** $\boldsymbol{R}$ **do**
  Generate a random population $\boldsymbol{P_i}$ of $\boldsymbol{N}$ solutions $\boldsymbol{x^{(i,1)}}, \boldsymbol{x^{(i,2)}}, \dots, \boldsymbol{x^{(i,1)}}$ where $\boldsymbol{x^{(i,j)}} = \left(\boldsymbol{x_1^{(i,j)}},\ \boldsymbol{x_2^{(i,j)}}, \dots, \boldsymbol{x_D^{(i,j)}}\right)$
  Compute the best fitness $\boldsymbol{B_i}$ and the worst fitness $\boldsymbol{W_i}$ of $\boldsymbol{P_i}$ of run $\boldsymbol{i}$ as follows:
  For $\boldsymbol{j} \leftarrow \mathbf{1}$ **to** $\boldsymbol{N}$ **do**
    Compute $\boldsymbol{f}\left(\boldsymbol{x^{(i,j)}}\right)$
    IF $\boldsymbol{j} = \mathbf{1}$ **THEN** $\boldsymbol{B_i} \leftarrow \boldsymbol{f}\left(\boldsymbol{x^{(i,j)}}\right)$ **ELSE IF** $\boldsymbol{B_i} > \boldsymbol{f}\left(\boldsymbol{x^{(i,j)}}\right)$ **THEN** $\boldsymbol{B_i} \leftarrow \boldsymbol{f}\left(\boldsymbol{x^{(i,j)}}\right)$ **END IF; END IF;**
    IF $\boldsymbol{j} = \mathbf{1}$ **THEN** $\boldsymbol{W_i} \leftarrow \boldsymbol{f}\left(\boldsymbol{x^{(i,j)}}\right)$ **ELSE IF** $\boldsymbol{W_i} < \boldsymbol{f}\left(\boldsymbol{x^{(i,j)}}\right)$ **THEN** $\boldsymbol{W_i} \leftarrow \boldsymbol{f}\left(\boldsymbol{x^{(i,j)}}\right)$ **END IF; END IF;**
  End For;

  Update global best and worst over all runs as follows:
  IF $\boldsymbol{i} = \mathbf{1}$ **THEN** $\mathbf{Best} \leftarrow \boldsymbol{B_i}$ **ELSE IF** $\boldsymbol{B_i} < \mathbf{Best}$ **THEN** $\mathbf{Best} \leftarrow \boldsymbol{B_i}$ **END IF; END IF;**
  IF $\boldsymbol{i} = \mathbf{1}$ **THEN** $\boldsymbol{Worst} \leftarrow \boldsymbol{W_i}$ **ELSE IF** $\boldsymbol{W_i} > \mathbf{Worst}$ **THEN** $\mathbf{Worst} \leftarrow \boldsymbol{W_i}$ **END IF; END IF;**
  $\boldsymbol{AVG} \leftarrow \boldsymbol{AVG} + \boldsymbol{B_i}$
End For;
$\boldsymbol{AVG} \leftarrow \boldsymbol{AVG}/\boldsymbol{R}$

$\boldsymbol{STD}$?
